1	DSC training	Differential scanning calorimetry is a thermoanalytical method in which the difference in the amount of heat required to increase the temperature of a sample and reference is measured as a function of temperature. Both the sample and reference are maintained at nearly the same temperature throughout the experiment. It analyses and enable the measurement of the transition such as a glass transition, melting and crystallisation. It can also be used to identify the contaminants and the solvent in the thermal analysis as the shifting in the melting temperature signal.	800.00/ pax/ day

2	TGA training	<p>BASED ON ASTM E1131, Thermogravimetric (TGA) analysis provides determination of endotherms, exotherms, weight loss on heating, cooling, and more. Materials analyzed by TGA include polymers, plastics, composites, laminates, adhesives, food, coatings, pharmaceuticals, organic materials, rubber, petroleum, chemicals and biological samples. TGA uses heat to force reactions and physical changes in materials. TGA provides quantitative measurement of mass change in materials associated with transition and thermal degradation. TGA records change in mass from dehydration, decomposition, and oxidation of a sample with time and temperature. Characteristic thermogravimetric curves are given for specific materials and chemical compounds due to unique sequence from physicochemical reactions occurring over specific temperature ranges and heating rates. These unique characteristics are related to the molecular structure of the sample.</p>	800.00/ pax/ day
